What is a inhaler used for?

Aerosols are used to deliver medication to the lungs. They are always metered-dose inhalers. The medication is stored inside the canister at pressures of approximately 20 to 40 psi.

How does it work?

When you press the inhaler, the medication is forced out under pressure through the nozzle. The nozzle is made of very fine metal which is designed to produce a mist of extremely small droplets. As the mist passes through your mouth and into your lungs, the medication is inhaled.

How do I use it?

1. Remove the cap from the inhaler. Hold the inhaler upright. Don’t shake the inhaler before use. If you shake the inhaler, the medication will get mixed up with the propellant and won’t come out properly.

2. Remove the cap from the mouthpiece. Take a deep breath. Hold your breath for about 5 seconds before releasing.

3. Take another deep breath, don’t hold your breath.

4. You can repeat the inhalation if needed.

Where do I buy it?
